A SERVICE PUBLICATION OF
LOCKHEED-GEORGIA COMPANY
A DIVISION OF
LOCKHEED AIRCRAFT CORPORATION

service news

Cover: Royal Australian Air Force C-l 30 Hercules over Sydney Harbor.

Vol. 3, No. 1, January – March 1976

CONTENTS

PRODUCT SUPPORT

DIRECTOR — T.J. CLELAND

CUSTOMER SERVICE DIVISION

MANAGER — D.L. BRAUND
FIELD SERVICE & INVENTORY MGMT — A.H. McCRUM
CUSTOMER TRAINING — A.R.LOVE
JETSTAR SUPPORT — H.L. BURNETTE
SPARES STORES & SHIPPING — J.K. PIERCE

CUSTOMER SUPPLY DIVISION

MANAGER — M.M. HODNETT
SUPPLY PROCUREMENT — R.C. WEIHE
SUPPLY SYSTEMS & INVENTORY CONTROL — C.K. ALLEN
SUPPLY SALES & CONTRACTS — H.T. NISSLEY. JR.
SUPPLY TECHNICAL SUPPORT — J.L. THURMOND

Pubhshed by Lockheed-Georgta Company, a Division of Lockheed Aircraft Corporation Information contained in this issue is considered by Lockheed-Georgta Company to be accurate and authoritative it should not be assumed however, that this material has received approval from any governmental agency or military service unless it is specifically noted This publication is for planning and information purposes only, and it is not to be construed as authority for making changes on aircraft or equipment, or as superseding any established operational or maintenance procedures or policies The following marks are registered and owned by Lockheed Aircraft Corporation: "[redacted]", "Lockheed", "Hercules", and "JetStar". Lockheed-Georga Company, Marietta, Georgia 30063

preformed packings

One of the most confusing and aggravating jobs faced by most mechanics is the finding, identifying, removing and replacing preformed packings, most often referred to as simply “O-rings”. This issue of the Service News is for those mechanics – to assist in cross-referencing part numbers, in determining dimensions, and in proper care and handling from storage to installation of preformed packings. We have also included some special listings for Hercules components to save you time.

Preformed Packings

Preformed packings such as O-rings were originally specified under AN (Air Force-Navy) specifications. As advances in aircraft design raised system operating temperatures and pressures, new materials for these packings were developed. These superior materials were adopted under MS (Military Standard) part numbers, replacing AN part numbers. As new fluids were developed and system requirements changed, O-ring manufacturers developed new material specifications, often under their own part numbers. Cross-referencing of part numbers became a problem.

Previous Page Table of Contents Next Page

AN and MS Standards

The need for specific materials for certain applications has been more critical for military aerospace equipment; thus, military drawings and specifications have been accepted as standard by diversified industries as well as aerospace industries.

The major manufacturers of preformed packings publish catalogues that list Air Force-Navy (AN) and Military Standard (MS) part numbers along with their own part numbers for the seals and packings meeting standard specifications. The military specification part numbers may be used to cross-reference one supplier's numbers to those of another source. Each manufacturer's or supplier's in-house numbering systems are unique, but as a rule they relate to standard designations established by military and public agencies.

Definitions

Before we talk about a chart of seals and components, let's define what we are talking about.

- A SEAL is a device meant to retain fluid (which includes air) within a component. A seal may consist of two or more parts, such as a packing in a gland (groove) with backup rings.

- A GASKET is a type of seal formed by crushing the packing material into the gland or open space such that the cavity is normally filled with the packing material.

- A PACKING is the component that, due to its plastic or elastic properties, does the sealing. The most common example is the O-ring.

- The GLAND is the cavity or inclusion that the packing (seal) fits in. It surrounds and supports the packing, controlling the squeeze.

- The SQUEEZE is the amount of distortion of the packing as it forms the seal in the gland.

- BACKUP RINGS are used to prevent pressure and friction from squeezing the O-ring packing through the clearance gap of a seal.

Substitution of Materials

In many packing applications one material can be substituted for another but the reverse substitution may not be recommended. As a general rule the newer materials are compatible with more different fluids than the older materials, and they can function over a wider range of temperatures. For example, MS28775-006 can function in temperatures from -65'F tn +275'F, and it supersedes three other specification/part numbers for hydraulic applications.

Part Numbers

The first attempt at standardizing part numbers for packings was the Air Force-Navy (AN) series of numbers. For example, AN6227B-1 is an O-ring for use in hydraulic systems. The dimensions of the O-ring are l/8-inch ID (inside diameter) and l/16 -inch W (width). AN numbers gave way to Military Standard (MS) numbers and dash numbers went from single digit to the present day three digit dash numbers. For example, MS28775-006 superseded AN6227B-1. A chart is necessary to cross-reference the different specification numbers. The Society of Automotive Engineers, Inc. published ARP 568 to standardize the dash numbering of O-rings. This publication has been superseded and cancelled by AS 568.

AS 568 establishes a standardized dash numbering system for O-rings. Each dash number is a three digit number and will be used as a part of the military or manufacturer's specification number to identify one nominal size O-ring. For example, no matter who manufactures the O-ring or what specification number is used, -001 is used to identify an O-ring with specific dimensions. AS 568 gives O-ring dimensions in decimal fractions of inches and millimeters. It is published by the Society of Automotive Engineers, Inc., 2 Pennsylvania Plaza, New York, N.Y. 10001.

Cross-Reference Chart

Our chart cross-references AN, MS, and some LS part numbers. The LS numbers are Lockheed Standard numbers developed for use in the design of the C-130 Hercules, C-141 StarLifter, C-140 JetStar, and/or the C-5A Galaxy.

Heading each of the part number columns in the chart is the first section of the part number for that series of packings. This basic number denotes the service and system specification for the material of the packing. Each dash number appearing below each series number identifies a standard size packing.

Chart IA gives the service specifications for rubber packings and seals. Chart 1B gives the service specifications for Teflon backup rings. Lockheed specifications for rubber O-rings are found in Chart 2, while Charts 3A and B are for cross-referencing rubber packings and Teflon backup rings by part number and dimensions. Chart 3C is a cross-reference by part number and tube size for packings and backup rings.

You will find some new basic part numbers in our service applications Charts 1A and 1B that are not included on our part number Chart 3A and 3B. These new packings conform to size and identification standards currently in use.

⚠1 Dash numbers correspond to those of AN6290 gasket. MS28778 supersedes and is equal to AN6290.

2. All dimensions in inches.

One of the newer, somewhat specialized designs for packings departs from the conventional O-ring cross section to form a T shaped cross section. The manufacturer, Greene, Tweed & Company, calls packings of this design G-T® Rings.

The G-T Ring arrangement prevents rolling of the packing and does an excellent job of sealing. The two backup rings carry most of the load. The unique feature in this new packing is the T shape of the rubber sealing material which can be molded from any of the standard materials. The backup rings are Teflon. This T shaped packing is never used without the two backup rings as shown in Figure 1.

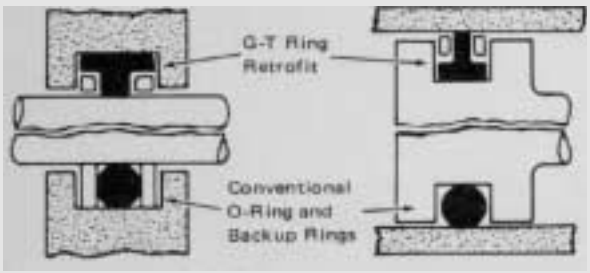

figure 1

The two special backup rings are necessary to complete the G-T Ring seal assembly. These backup rings are preformed to fit into the spaces on each side of the stem of the T, making it practically impossible for the rubber ring to roll or to extrude even under extreme conditions of dryness and high pressure (Figure 2).

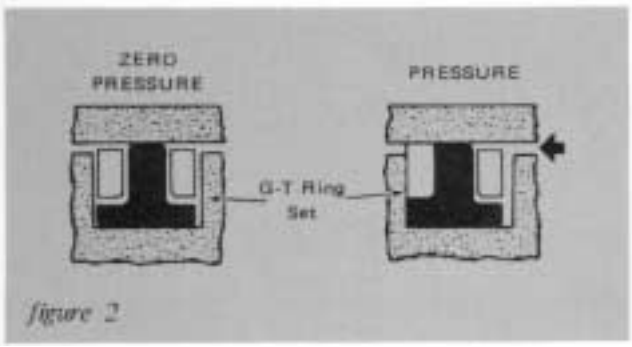

figure 2

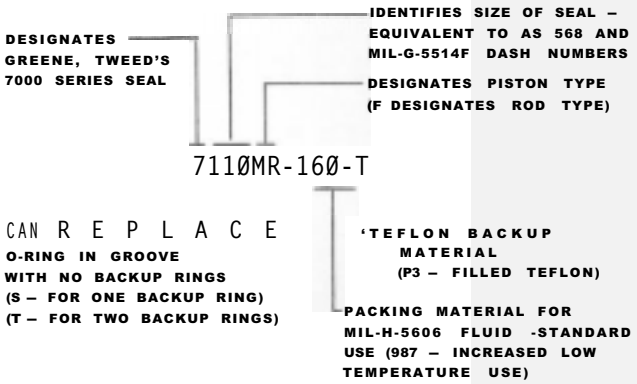
The G-T Ring was originally tested by Lockheed-Georgia Company for application in the Hercules ramp actuating cylinder. This cylinder had always been plagued by rolling O-rings because of two factors: (1) the rod is excessively long so we are dealing with a very long stroke; (2) the ramp, when open, exposes this long rod to the drying effect of the atmosphere. These two conditions caused excessive seal rolling in this actuator. Since the change to Greene, Tweed & Company seals, we have had no reported cases of seal rolling.

The G-T Ring seal proved to be vastly superior to any other seal tested. Its success in the tough application on the ramp actuators subsequently led to its installation on all of our long and medium stroke hydraulic actuators.

The following is a breakdown of the manufacturer's part number structure for Greene, Tweed & Company seals:



The makeup of a part number for a G-T Ring listed in a special kit may be different from that shown in our example. For instance, the shaft seal in the JetStar MLG actuator is P/N 222FT-160A-T. This number retains most of the characteristics of our example. The numbers for the Hercules ramp actuator shaft seal are unique in form; also, the packing and backup rings are numbered separately (reference G-T Ring Chart). Notice that G-T Ring part numbers are inconsistent with military specification numbers; in fact, early G-T numbers are inconsistent with present day numbers.

Our brief analysis of the manufacturer's part number makeup for G-T Ring assemblies is intended to help you become generally familiar with them. You can make comparisons to see how this unique G-T Ring design fits in with the O-ring inventory if you know the width of the groove provided for the O-ring. Does the original groove accommodate no backups, one backup or two backups? Lockheed recommends (as does the manufacturer) that you get engineering assistance before you substitute a G-T Ring for a conventional seal.

GREENE, TWEED SEALS USED IN THE HERCULES

The following is a partial listing of those Hercules components using G-T Rings, along with the part number for the seals. Only the G-T Rings are listed. Consult the applicable overhaul manuals for the components to finish out the list of seals needed and the procedures for replacing the seals.

G-T RING CHART

COMPONENT	PART NUMBER	G-T RING SET PART NUMBER
Aft Cargo Door Actuator	370749-1	721 D5FT-987-P3
Ramp Actuator	370750-1	32A8FT-160A Rubber Packing 32A8FT-2T Backup Ring (2 ea)
Snubber-Aft Cargo Door	5C5794 (Ronson)	7329MT-160-N 7222MT-160-N 7215FT-160-N 7112FT-160-N

* Out of production.

** Also included in cure date kits for replacement in all previously supplied nose and main gear struts.

SERVICING HERCULES HYDRAULIC FILTERS

In answer to a request from the field, the part numbers for seals and rings for Hercules hydraulic filters have been organized into one table for easy reference. New seals and rings are to replace the old ones each time the filter elements are serviced. (See page 16 for chart.)

Some drawings carry AN (Air Force-Navy) part numbers which later changed to MS (Military Standard) numbers. In these cases we include both numbers. One of the parts for the engine pressure filter has a vendor part number because it is not interchangeable with similar parts manufactured to industry standard drawings.

SERVICING INSTRUCTIONS FOR HYDRAULIC FILTERS

- Empty all contaminants from bottom of filter bowl.
- Rinse bowl with clean MIL-H-5606 hydraulic fluid (red oil).
- Inspect new O-ring to ensure that it is not nicked or chipped.

  Lubricate O-ring with clean MIL-H-5606.
- Install O-ring and backup rings being very careful not to nick or pinch the O-ring – remember, most seal leaks are caused by damage at installation.
- Lubricate the threads on the bowl and housing head with MIL-H-5606.
- Fill engine pressure line filter bowl with fluid to displace air.
- Screw bowl into head again being careful that seals are properly seated prior to assembly.
- Pressure check during normal function of system.

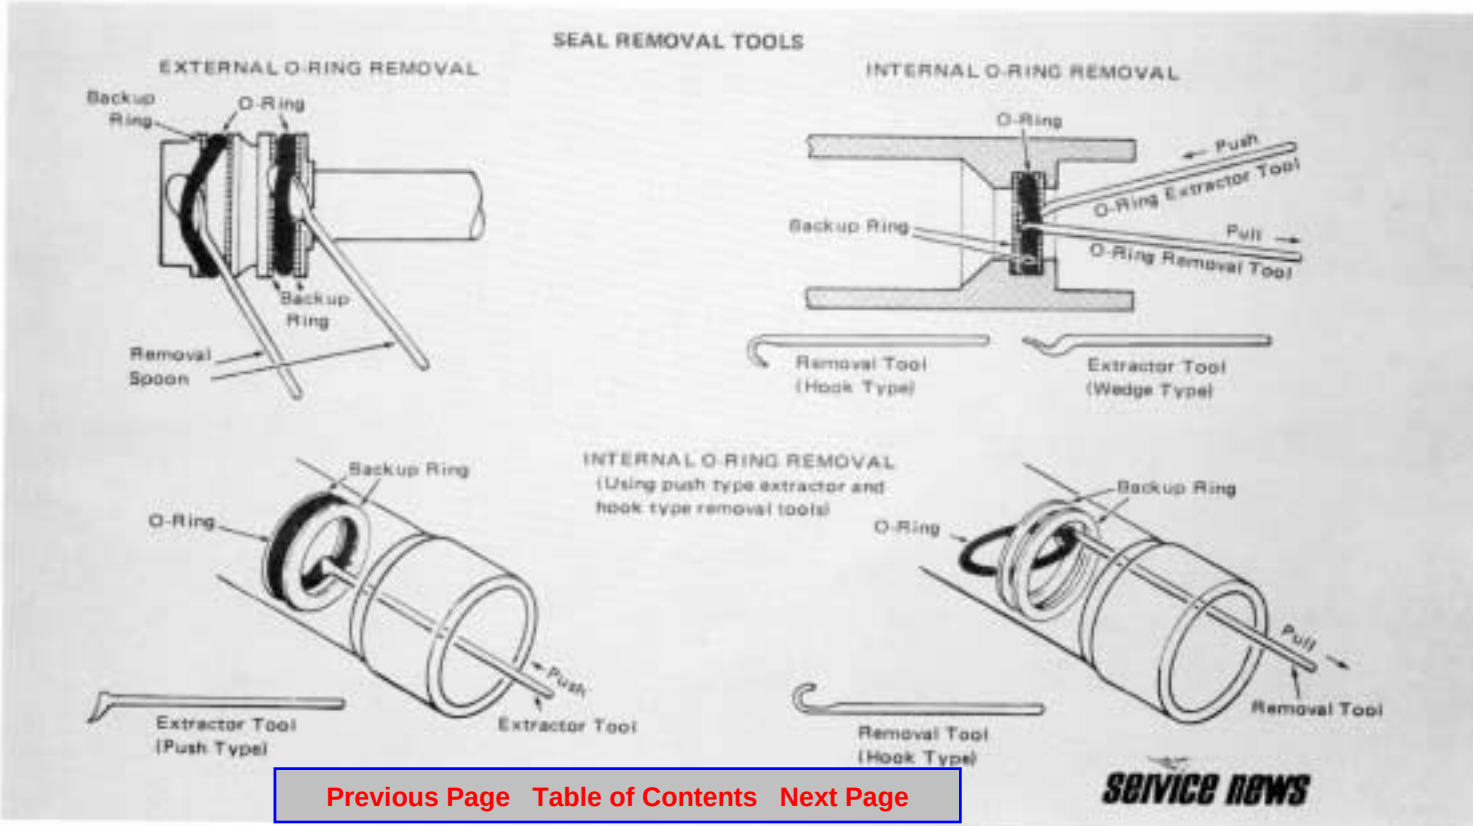
NOTE

Reuse of packings and gaskets is considered poor maintenance practice. Mutilate and discard all removed (used) packings and gaskets.

CARE AND HANDLING OF PREFORMED PACKINGS

Preformed packings can do their job of sealing only if they are given proper care and handling in storage, removal, and installation. Here are some tips on handling packings:

- Packings can become deformed as a result of poor storage — don't stack parts and containers in a manner that will damage the seals.
- Creasing of seals results from force applied by sharp edges and by squeezing between boxes.
- Flattening of seals can result from storing under heavy parts.
- Deformation of seals can result from hanging packings on nails or pegs.
- Contamination can result from leaking fluids, dirt, etc., coming in contact with the seals.
- Keep packings in their containers until used.
- Be mindful of cure date and shelf life.
- USC the correct tool in the removal and installation of packings. A variety of tools may be used for a given job. Aluminum, brass, phenolic, plastic or other suitable soft material may be used to make the tools. Avoid sharp edges, and be careful of nicks and scratches on the component such as rod ends, caps, pistons, where the seal fits.



nose wheel SHIMMY

and what to do about it

by Bob McRay, *Service Representative*

Most Hercules maintenance personnel know that there are at least fifteen items on a Hercules nose landing gear that can cause or contribute to nose wheel shimmy. The problem is how to go about isolating the shimmy to an item, component, or area without expending considerable time and effort on costly trial and error replacements and adjustments.

One method that is simple, accurate, relatively easy, and has been used quite successfully in the field requires the assistance of a flight crew, and entails only a taxi run during which a couple of observations are made and recorded. It is accomplished as follows:

Taxi at a speed just sufficient to allow the nose wheels to be lifted off the ground (just a few seconds will do), and make these notations:

(1) Did the shimmy stop while the nose wheels were off the ground or did it continue?

(2) During the taxi run with the wheels on the ground did the steering wheel pointer move back and forth rapidly during shimmy or was it relatively steady?

CAUTION

IF REPEATED TAXI RUNS ARE NECESSARY, BRAKES SHOULD BE ALLOWED TO COOL BETWEEN RUNS.

That's it. Taxi back to the work area and look at your notes.

If the shimmy continued with the wheels off the ground, wheel and/or tire unbalance is indicated. Check for worn spots on the tires and any other condition on the wheels or tires that may contribute to an unbalanced condition. Recaps, if used at your facility, should be highly suspect, since it is a difficult task to balance recapped tires.

If the shimmy ceased at nose liftoff, then observations noted in item (2) during the taxi run must be considered:

- *If the shimmy produced no noticeable movement at the steering wheel pointer with wheels on the ground,* looseness, caused by excessive wear in certain mechanical areas, is indicated. First, check the torque arms (scissors). The upper, lower, and center attach bolts and bushings are subject to wear and, if the wear is excessive, will cause a violent shimmy at all speeds up to liftoff. Special attention should be given to the fact that one bolt and/or bushing location may be within the wear tolerances, but it is the sum of the wear on all the associated bolts and bushings that should be of concern. Next, check the steering actuators' rod end bearings for wear and the bolts for security of mounting. Last, and this will require jacking the nose of the aircraft, check for worn wheel bearings and proper axle nut torque.

- *If the steering wheel pointer did move back and forth during the shimmy,* a problem concerning the steering control valve is indicated. Here's why: The steering control valve is unique in that it will accept steering commands from either the steering wheel or from the nose gear, permitting certain types of shimmy to be fed back through the valve to the steering pointer. Since the pointer is connected directly to the steering control valve shaft by the rocker arm and cables, it will be displaced anytime the shaft is displaced. Steering wheel pointer movement during shimmy narrows our check to two areas: tires and the control valve.

Previous Page Table of Contents Next Page

(1) **Check the tires.** Uneven tire pressures and dissimilar or faulty tread designs tend to make a tire move in irregular patterns. This irregular movement is transmitted through the scissors to the control valve and, as speed increases, so does the irregular movement, or shimmy.

(2) **Next, check the valve itself.** The relief valve, P/N 341640, could be sticking in the open position due to burrs on the stem. (T.0. 4SA3-26-3 has been amended to include rework of this stem during overhaul.) One method of checking for this condition is to remove the plug (item 4, Figure 3, T.O. 4SA3-26-3 dated 20 January 1975) in the manifold side of the steering valve and install an MS 21916D6-4 reducer, MS28762-4 hose, P/N 695767-l snubber, appropriate adapter, and a O-500 PSI pressure gage (see illustration). Disconnect the scissors and, using hydraulic pressure from the auxiliary system, rotate the steering mechanism by turning the steering wheel at a very slow but constant rate of turn from center to extreme. This should take approximately 10 seconds. Pressure on the gage should be maintained at 70 PSI plus or minus 20 PSI.

Pressure readings outside these limits indicate a sticky or leaking relief valve assembly. Since the valve is an integral part of the spring loaded accumulator, it requires replacement of the complete steering control valve.

That's the troubleshooting procedure. It may sound lengthy and difficult, but if you concern yourself with the mechanics of the overall nose gear and its relationship to the steering mechanism, it's as easy as 1,2,3.

To **sum up:**

(1) Shimmy with wheels off the ground – tire and wheel unbalance.

(2) Shimmy with wheels on the ground and no pointer movement – bolts, bushings and bearings wear.

(3) Shimmy with wheels on the ground with pointer movement – steering control valve, uneven tire pressures, tread imperfections, or unlike tread designs.

One last thing – and I'll bet you caught it – the taxi check could be eliminated if the flight crew would make these observations for you when the problem occurs, and note them in the flight forms.
